### 2-2

- (a) 74155 Similar to two decoders as in Fig 2-2.
- (b) 74157 Similar to multiplexers of Fig. 2-5,
- (C) 74194 Similar to register of Fig. 2-9.
- (d) 74163 Similar to counter of Fig. 2-11.

2-5 Remove the inverter from the E input in Fig. 2-2(2).

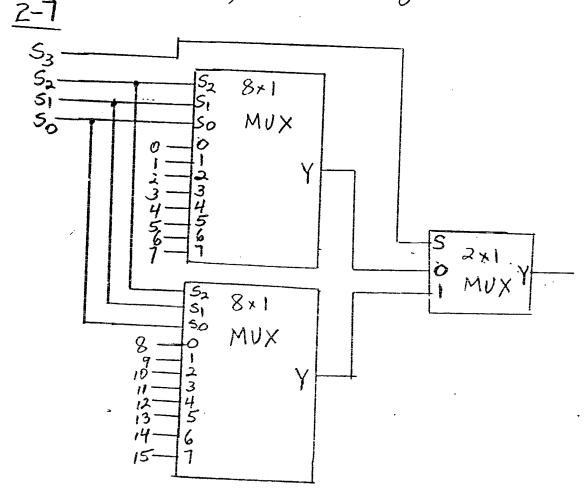

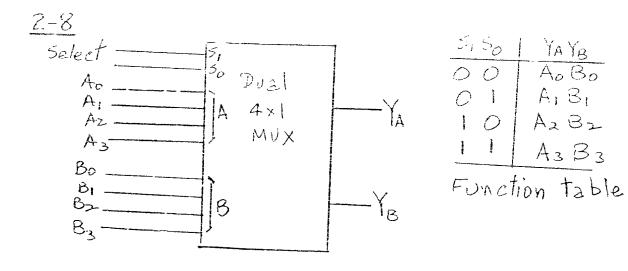

or if only  $D_0 = 1$ :

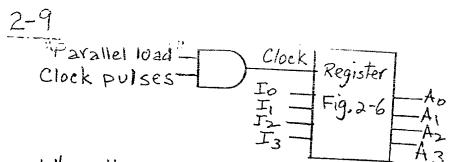

the outputs  $A_0 A_1 A_0 = 000$ Needs one more output

to recognize the all

zeros input condition.

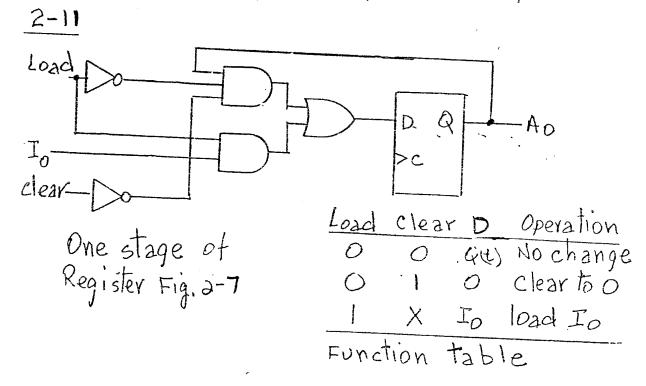

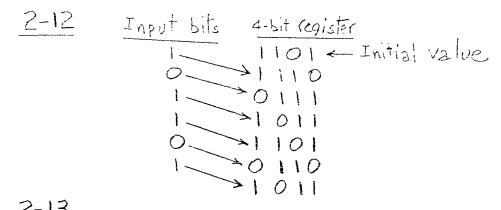

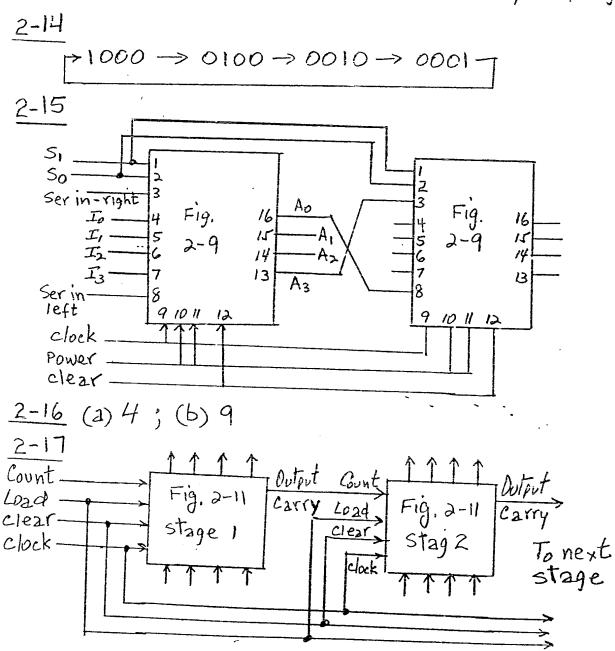

When the Parallel load input=1, the clock pulses go through the AND gate and the data inputs are loaded into the register. When the Parallel load input=0, the output of the AND gate remains at O.

2-10
The buffer gate does not perform logic. It is used for signal amplification of the clock input.

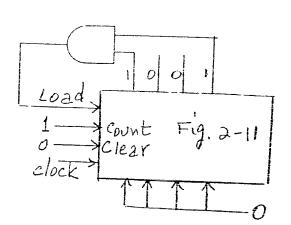

serial transfer: One bit at a time by shifting.
Parallel transfer: All bits at the same time.
Input serial data by shifting-output data in parallel.
Input data with parallel load - Output data by shifting.

2-18 After the count reaches N-1=1001 the register loads 0000 from inputs.

2-19

P'Q: R1←R3

#### 4-4

Connect the 4-line common bus to the four inputs of each register.

Provide a "load" control input in each register.

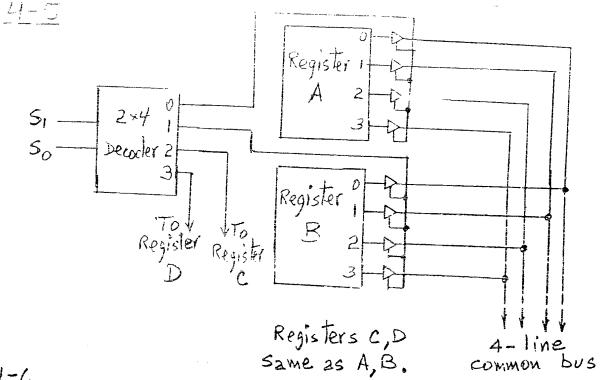

Provide a clock input for each register.

To transfer from register C to register A:

Apply S, So = 10 (to select C for the bus,)

Enable the load input of A

Apply a clock pulse.

(a) 4 selection lines to select one of 16 registers.

(b) 16 x1 multiplexers

(c) 32 multiplexers, one for each bit of the registers.

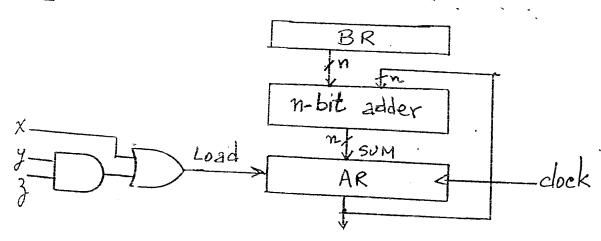

4-7

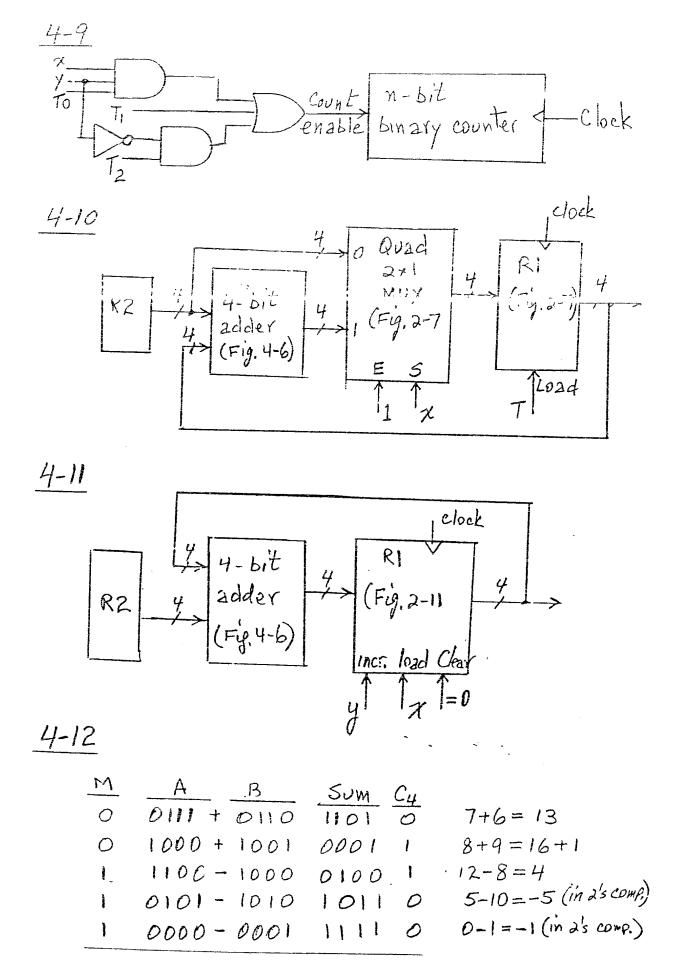

(2) Read memory word specified by the address in AR into register R2.

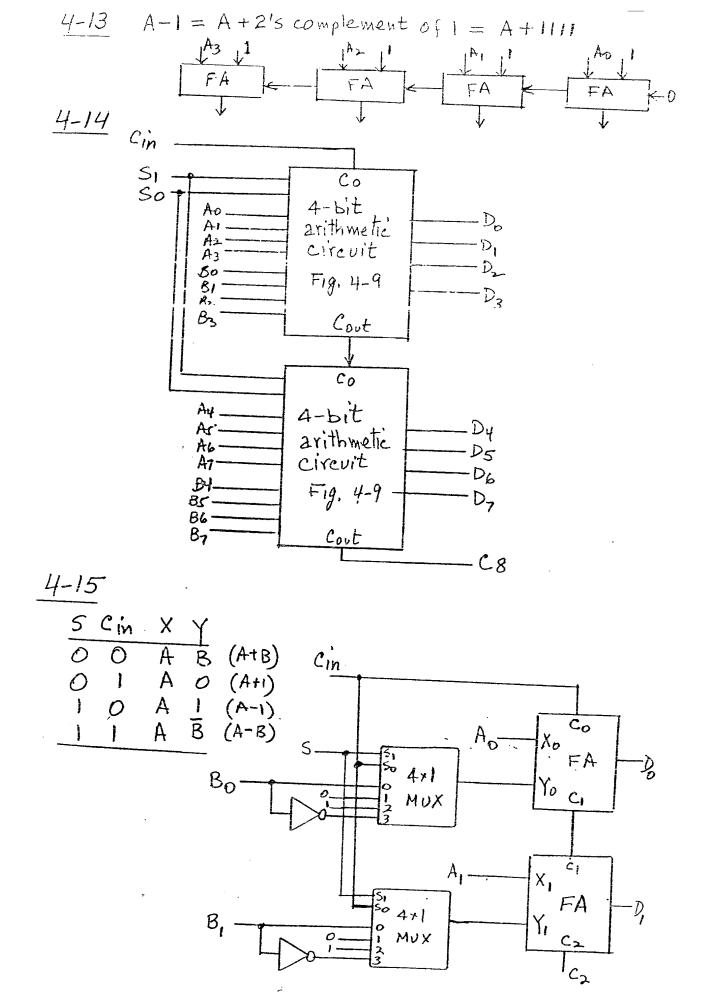

(b) Write content of register R3 into the memory word specified by the address in AR.

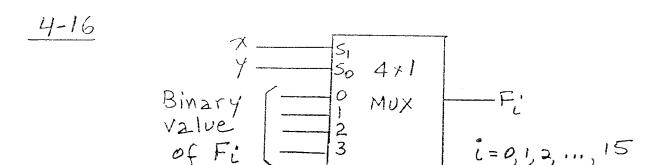

(e) Read memory word specified by the address in R5 and transfer content to R5 (destroys previous value)

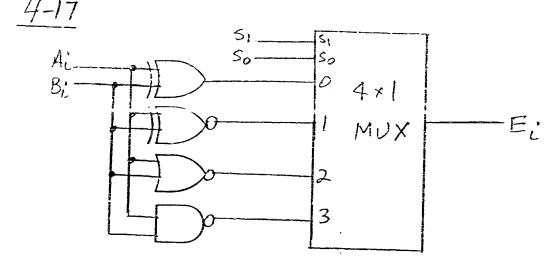

(a) 
$$A = 11011001$$
  
 $B = 10110100$   
 $A \leftarrow A \oplus B 01101101$ 

(a) 
$$A = 11011001$$
  $A = 11011001$   $A = 11011001$   $B = 11111101$   $A = AVB$ 

(2)

Converts the ISZ instruction from a memory-reference instruction to a register-reference instruction.

The new instruction ICSZ can be executed at time T3 instead of time T6, a saving of 3 clock cycles.

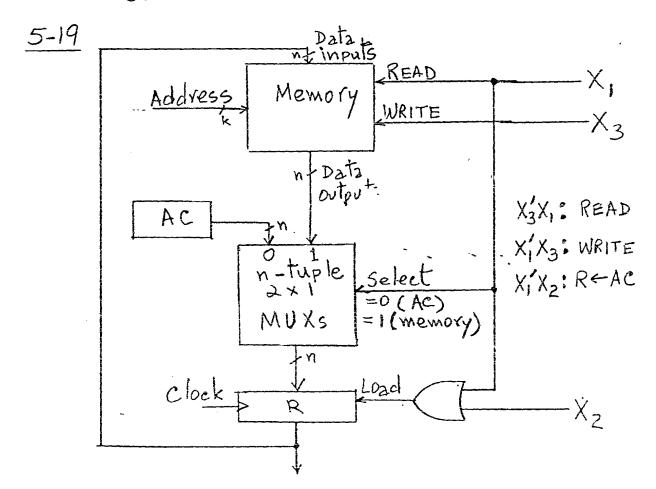

(a) To TO a NATOOT Day Do
(c) To: IR = M[PC] PC = PC+1
T: AR (e-7) < M[PC], PC < PC+
T: AR(8-15) = M[PC], PC=PC+
T3: DR & M[AR]

- 1. Read 40-bit double instruction from memory to IR and then increment PC.
- 2. Decode opeode 1.
- 3. Execute instruction I using address 1.
- 4. Decode opende 2.
- 5 Frecute instruction 2 using address 2,
- 6. Go back to stop 1.

- (a) BUN 2300
- (b) ION
  BUN O I (Branch indirect with address 0)

5-21 From Table 5-6: (ZDR=1 if DR=0; ZAE=1 if AC=0)

INR(PC) = R'T, + RT2+D6T6 ZDR + P.Bq(FGI) + PB8(FGO)

+ YB4 (AC15)'+YB3 (AC15)+YB2ZAC+YB, E'

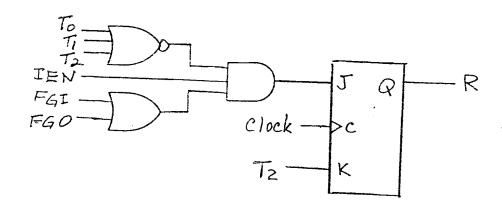

LD(PC) = D4T4 + D5T5

CLR(PC) = RT1

The logic diagram is similar to the one in Fig. 5-16,

5-22 Write = D3T4 + D5T4+D6T6+RT, (M[AR] ←xx)

5-23 (To+T,+T2)(IEN)(FGI+FGO); R←1 RT2: R←0

5-24
The Places PC outs the bus, From Table 5-6;

R'TO : AREDC

RTO: TREPC

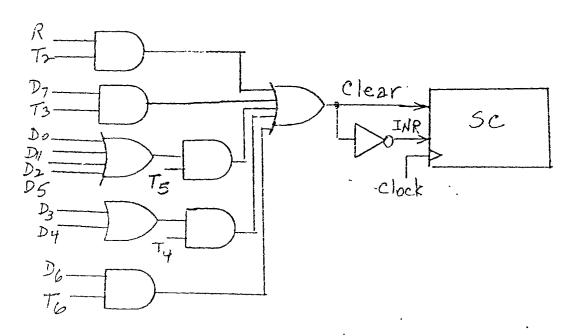

D5T4: M[AF] - PC

 $\chi_2 = R'T_0 + RT_0 + D_5T_4 = (R+R)T_0 + D_5T_4 = T_0 + D_5T_4$ 

5-25 From Table 5-6:

 $CLR(SC) = RT_3 + D_7T_3(I+I) + (D_0+D_1+D_5+D_5) T_5 + (D_3+D_4)T_4 + D_6T_6$ 

6-4 A line of code such as: LDA I is interpreted by the assembler (Fig. 6-2) as a two symbol field with I as the symbolic address. A line of code such as: LDA I I is interpreted as a three symbol field. The first I is an address symbol and the second I as the Indirect bit. Answer: Yes, it can be used for this assembler.

6-5

The assembler will not detect an ORG or END if the line has a label; according to the flow chart of Fig. 6-1. Such a label has no meaning and constitutes an error. To detect the error, modify the flow chart of Fig. 6-1:

6-6 (a) memory characters Hex binary

# CHAPTER 7

A microprocessor is a small size CPU (computer on a chip) Microprogram is a program for a sequence of micropperations. The control unit of a microprocessor ean be hardwired or microprogrammed, depending on the specific design. A microprogrammed computer does not have to be a microprocessor.

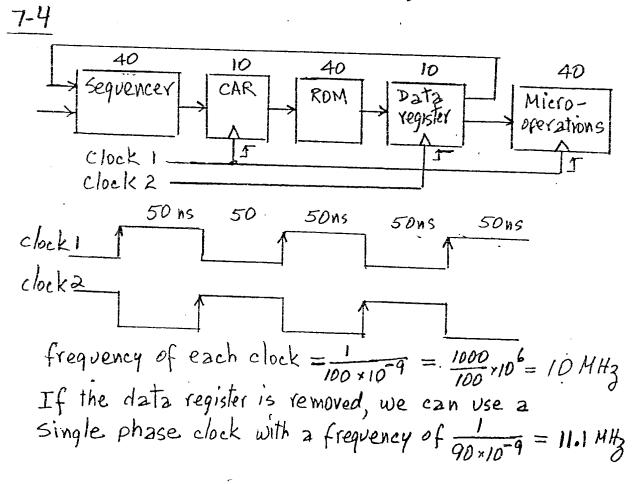

7-2 Hardwired control, by 4k finition, does not contain a Control memory.

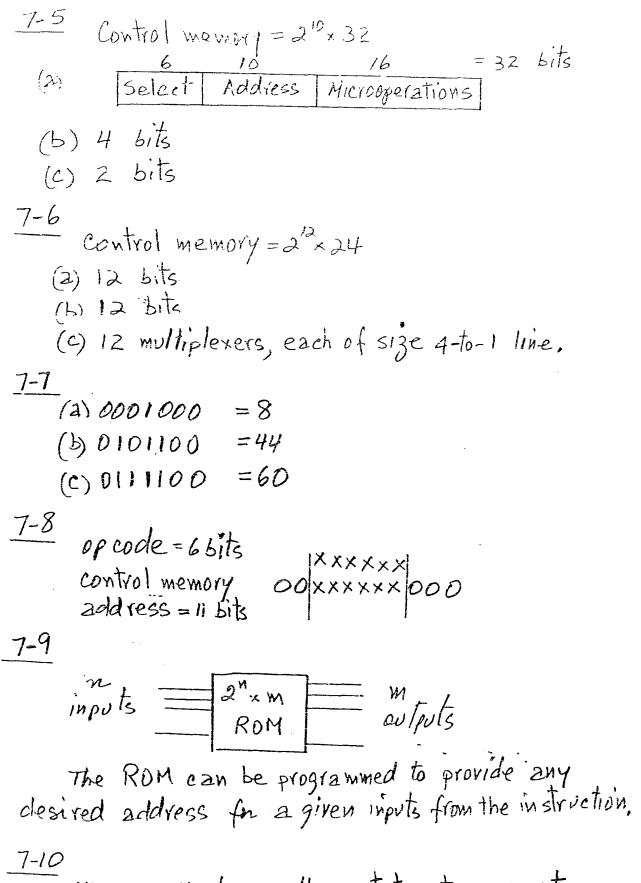

Micropperation - an elementary digital computer operation.

Microinstruction - an instruction stored in control memory.

Microprogram - a sequence of microinstructions,

Microcode - same an microprogram.

Either multiplexers, three-state gates, or gate logic (equivalent to a mux) are needed to transfer in formation from many sources to a common destination.

7-12

(a) READ DR = M[AR] F2 = 100 000 100 101

DRTAC AC = DR F3 = 101

(b) ACTDR DREAC F2=101 000 100 101 DRTAC ACC-DR F1=100

(C) ARTPC PC = AR F3=110

DRTAC AC = DR F1=100 | Impossible.

WRITE M[AR] = DK F1=111 | Both use F1

If I=0, the operand is read in the first microinstruction and added to AC in the second.

If I=1, the effective address is read into DR and control goes to INDR2. The Subroutine must read the operand into DR.

INDRZ: DRTAR U JMP NEXT READ U RET -

7-14

(2) Branch if S=0 and Z=0 (positive and non-zero AC) - See last instruction in Problem 7-16.

(k-n	ا – ا	1) t	. ρ =	= 6	5 7.	8-	- ] :	= /	3	cyc	1/25			

 $\frac{9-3}{k=6} = 6 \text{ segment} (k+n-1) = 6+200-1 = 205 \text{ cycles}$  n = 200 tasks (k+n-1) = 6+200-1 = 205 cycles

$$\frac{9-4}{t_n = 50 \text{ ns}} \qquad S = \frac{n t_n}{(k+n-1)t_n} = \frac{100 \times 50}{(6-99) \times 10} = 4.76$$

$$t_p = 10 \text{ ns}$$

$$t_p = 100$$

$$S_{\text{wax}} = \frac{t_n}{t_p} = \frac{50}{10} = 5$$

(a) 
$$t_p = 45 + 5 = 50 \text{ ns}$$
  $k = 3$ 

(c) 
$$S = \frac{m t n}{(k+n-1) t_p} = \frac{10 \times 100}{(3+9)50} = 1.67$$
 for  $n = 100$   

$$= \frac{100 \times 100}{(3+99)50} = 1.96$$
 for  $n = 100$   
(d)  $S_{\text{max}} = \frac{t n}{t_0} = \frac{100}{50} = 2$ 

- (2) See discussion in Sec. 10-3 on array multipliers. There are 8x8=64 AND gates in each segment and an 8-bit binary adder (in each segment).
- (b) There are 7 segments in the pipeline

(c) Average time = 
$$\frac{k+N-1}{n}t_p = \frac{(n+6)30}{n}$$

For n = 10 tav = 48 ns

For M=100 tav=31.8 ms

For n→∞ tAV=30 ns

To increase the speed of multiplication, a carrysave (Wallace tree) adder is used to reduce the propagation time of the carries.

9-7

(a) Clock cycle = 95 + 5 = 100 ns (time for segment 3) for n = 100; k = 4,  $t_p = 100 \text{ ns}$ .

Time to add 100 numbers =  $(k+n-1)t_p = (4+99)100$ = 10,300 ns = 10,3 µs

(b) Divide segment 3 into two segments of 50+5=552nd 45+5=50 ns, This makes  $t_p=55$ ns; k=5 $(k+n-1)t_p=(5+99)55=5,720$ ns=5,72Ms 9-8 Connect output of adder to input Exabin a feedback path and use input Ax22 for the data X, through X100. Then use a scheme similar to the one described in conjunction with the adder pipeline in Fig. 9-12.

One possibility is to use the six operations listed in the beginning of Sec. 9-4.

See Sec. 9-4: (1) prefetch target instruction;

(b) use a branch target buffer; (c) use a loop buffer; (d) use branch prediction.

(Delayed branch is a software procedure)

9-11

1. Load RIE M[312]

2. Add RZERZHM[313]

3. Increment R3

4. Store M[314] = R3

10-16 The algorithm for square-root is similar to division with the radicand being equivalent to the dividend and a "test value" being equivalent to the divisor.

Let A be the radicand, Q the square-root, and

R the remainder such that  $Q^2 + R = A$  or:

JA = Q and a remainder

General coments:

1. For k bits in A (keven), Q will have 1/2 bits: Q = 9,9293...94/2

2. The first test value is 01

The second test value is 19,01

The third test value is 009,9201

The fourth test value is 0009,929301 etc.

3. Mark the bits of A in groups of two starting from left.

4. The procedure is similar to the division restoring method as shown in the following example:

91 92 93 94
1 1 0 1 = Q = 13

V10 10 10 01 = A = 169

OI Subtract first test value 01

Answer positive; let 91=1

O1 10 bring down next pair

O1 01 answer positive; let 92=1

O0 01 10 bring down next pair

O0 01 10 subtract third test value 009,901

negative answer negative; let 93=0

O0 01 10 oring down next pair

10-17 (a) e = exponent e+64 = biased exponent

(b) The biased exponent follows the same algorithm as a magnitude comparator See Sec. 9-2

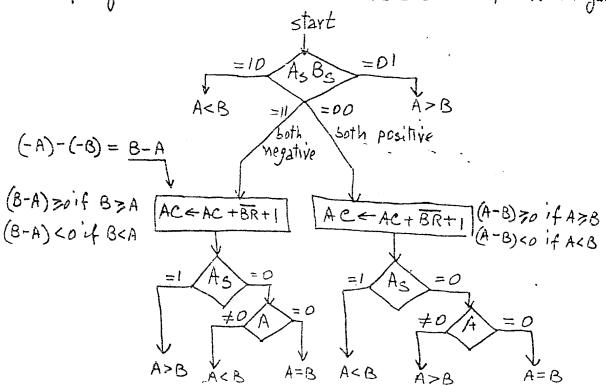

(c)  $(e_1 + 64) + (e_2 + 64) = (e_1 + e_2 + 64) + 64$ subtract 64 to obtain biased exponent sum

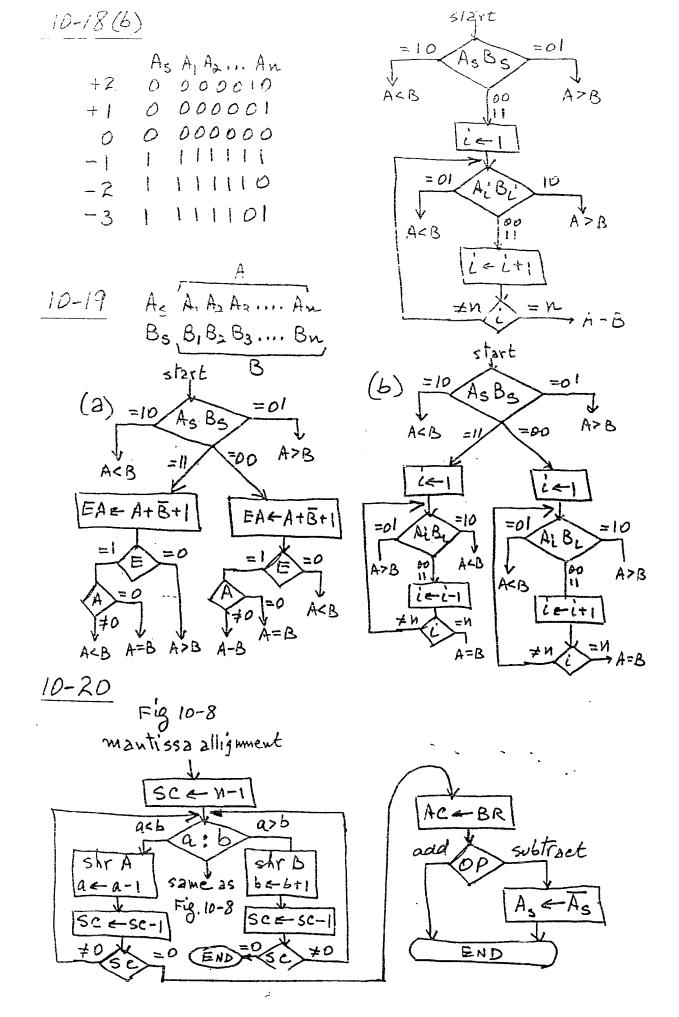

(d)  $(e_1+64)-(e_2-64)=e_1+e_2$ add 64 to obtain biased exponend difference,

10-18

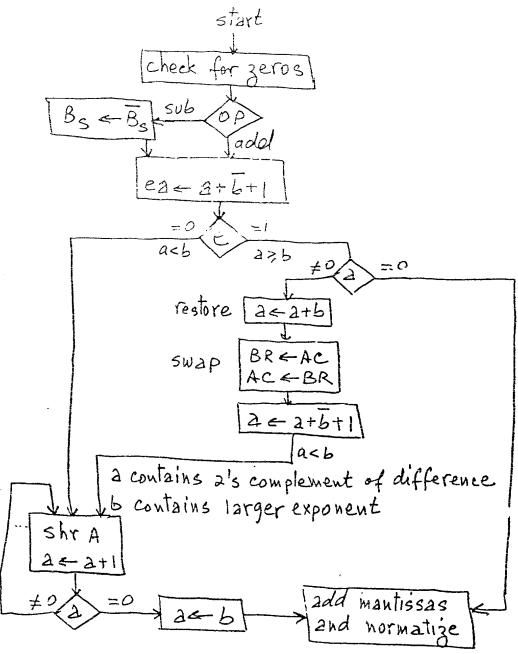

(a) 
$$AC = A_5 A_1 A_2 A_3 ... A_n$$
  
 $BS = B_5 B_1 B_2 B_3 ... B_n$ 

If signs are unlike - the one with a O (plus) is larger. If signs are alike - both numbers are either positive or negative

10-21 Let "e" be a flip-flop that holds end-carry after exponent addition,

10-22

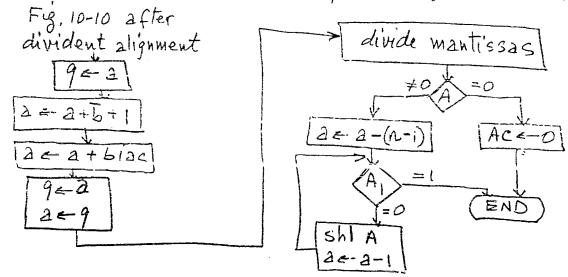

when 2 numbers of n bits each are multiplied, the product is no more than an bits long - see Prob. 9-7.

$$\frac{10-23}{\text{divisor}} \frac{\text{dividend}}{\text{divisor}} A = 0.1 \times \times \times \text{ where } x = 0,1$$

(a) If ACB then after shift we have A=1. xxxx and 1st quotient bit is 21.

(6) if AZB, dividend alignment results in A = 0.01 xxxx then after the left shift A>B and first quotient bit = 1.

Remainder bits rrrrr have a binary-point (n-1) bits to the left.

#### 10-25

- (a) When the exponents are added or incremented
- (b) When the exponents are subtracted or decremented
- (c) Check end-carry after addition and carry after increment or decrement.

#### 10-26

Assume integer mantissa of n-1=5 bits (excluding sign)

(2) Product: A Q

XXXXX XXXXX. #28

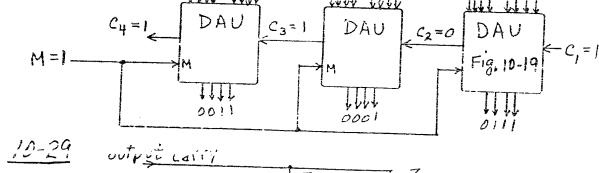

Product in AC: XXXXX. #28+5 - binary-point for integer

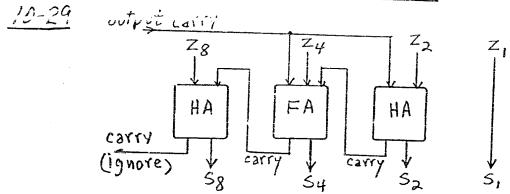

(b) Single precision normalized dividend: xxxxx. \* 28

Dividend in AQ: A Q

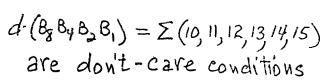

xxxxx 00000. \* 23-5

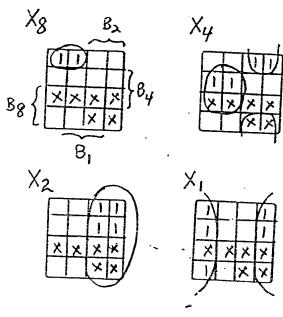

10-27
Neglect Be and Ae from Fig. 10-14. Apply carry directly to E.

10-32. The excess-3 code is self-complementing code. Therefore, to get 9's complement we need to-complement each bit.

M=0 for 
$$x = B$$
  
M=1 for  $x = 9$ 's comp. of  $B$   
M Bi |  $x_i = B_i \oplus M$   
O O | O |  $x_i = B_i$ 

$$\begin{array}{c|c} & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & &$$

Algorithm is simalar to flow chart of Fig. 10-2

$$\frac{10-35}{32} = 52 + \frac{16}{32}$$

$$B = 032$$
  
 $B+1 = 968$  (10's comp.)

- (a) At the termination of multiplication we shift right the content of A to get zero in Ae.
- (b) At the termination of division, B is added to the negative difference. The negative difference is in 10's complement so Ae = 9. Adding Be = 0 to Ae = 9 produces a carry and makes Ae = 0.

## 10-37

change the symbols as defined in Table 10-1 and use same algorithms as in Sec. 10-4 but with multiplication and division of mantissas as in Sec. 10-5.

#### CHAPTER 11

11-25

76= (01001100), Replace the six O's by 010011, xy

11-26

Set the mask bit belonging to the interrupt source so it can interrupt again. At the beginning of the service routine, check the value. of the return address in the stack. If it is an address

within the source service program, then the same

source has interrupted again while being serviced,

11-21

The service routine checks the flags in sequence to determine which one is set, The first flag that is cheeked has the highest priority level. The priority level of the other sources corresponds to the order in which the flags are checked.

When the CPU communicates with the DMA controller, the read and write lines are used as inputs from the CPU to the DMA controller.

When the DMA controller communicates with memory, the read and write lines are used as outputs from the DMA to memory.

11-28

(a) CPU initiates DMA by transferring:

256 to the word count register.

1230 to the DMA address register.

Bits to the coutrol register to specify a write operation.

(b) 1. I/o device sends 2 "DMA request."

a. DMA sends BR (bus request) to CPU.

3. CPU responds with a BG (bus grant).

4. Contents of DMA address register are placed in address bus.

5. DMA sends "DMA acknowledge" to I/o device and enables the write control line to memory.

6. Data word is placed on data bus by I/o device,

7. Inrement DMA address register by 1 and Decrement DMA word count register by 1

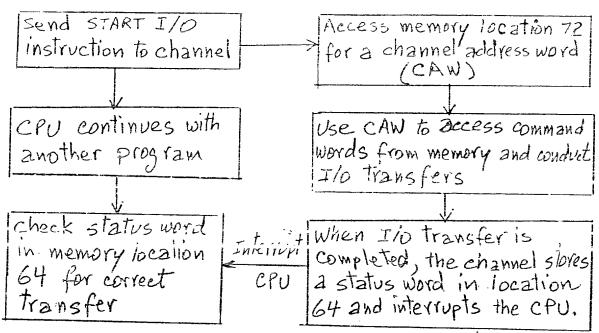

8. Repeat steps 4-7 for each data word transferred

11-29

every 1 µsec. (106). Characters arrive one every 1/2400 = 416.6 µsec. Two characters of 8 bits each are packed into a 16-bit word every 2 × 416.6 = 833.3 µsec. The CPU is slowed down by no more than (1833,3) ×100 = 0.12%.

11-30

The CPU can wait to fetch instructions and data from memory without any damage occurring except loss of time, DMA usually transfers data from a device that cannot be stopped since information continues to flow so loss of data may occur.

11-32 There are 26 letters and 10 numerals.  $26 \times 26 + 26 \times 10 = 936$  possible addresses,

The processor transmits the address of the terminal followed by ENQ (enguiry) code popo 0101. The terminal responds with eithe ACK (acknowledge) or NAK (negative acknowledge) or the terminal does not respond during a timeout period. If the processor receives an ACK, it sends a block of text.

# CHAPTER 13

13-1

Tightly coupled multiprocessors require that all processes in the system have access to a common global memory. In loosely coupled multiprocessors, the memory is distributed and a mechanism is required to Provide wessage - passing between the processors. Tightly coupled systems are easier to program. Since mu special sleps are required to make shared data available to two or more processors. A loosely crupted system required that sharing of data be implemented by the messages.

13-2

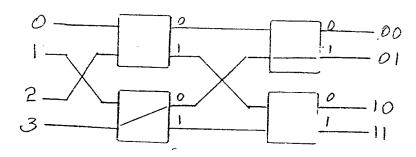

The address assigned to common memory is never assigned to any of the local memories. The common memory is recognized by its distinct address.

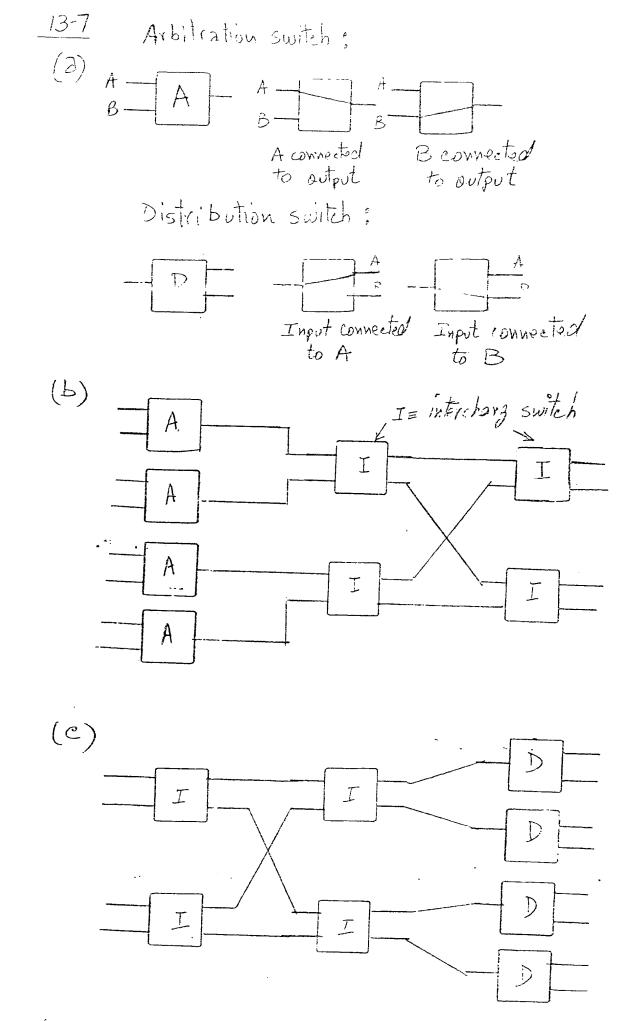

13-3 Pxm switches

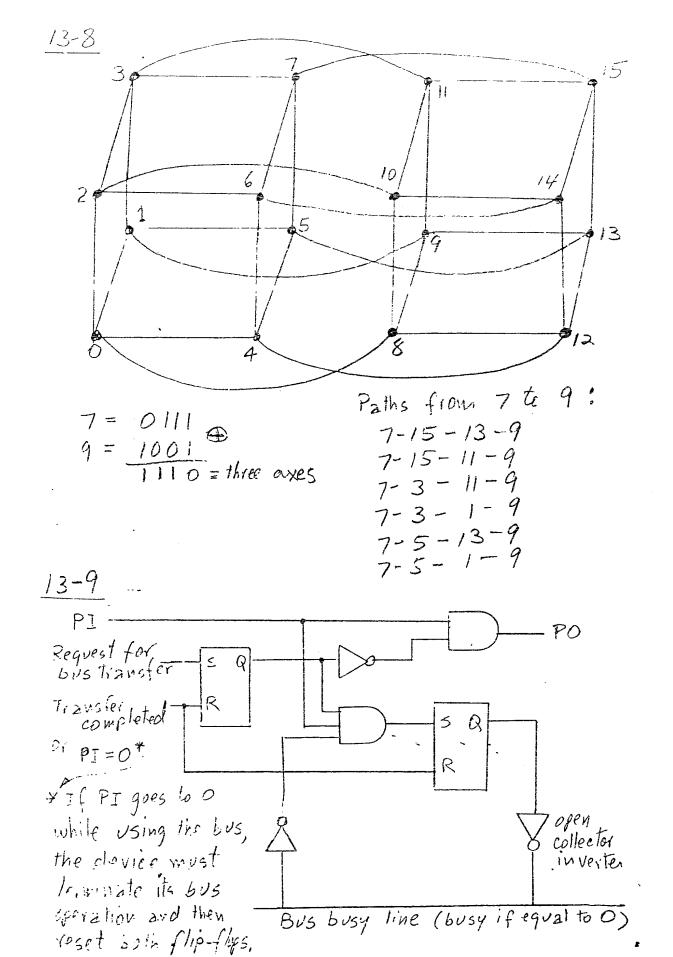

13-4 logn stages with n switches in each stage.

Inputs 0,2,4, and 6 will be disconnected from outputs 2 and 3.

13-6

Encoder input
Encoder autput
Decoder infut
Decoder output

OI (II has highest priority)

13-11

As explained in the text, innect output Po from arbiter 4 into input PI of artitle 1. Over the livie is disabled, the artitle that releases the bus has the lowest pricity.

13-12

Memory access needed to send data from one processor to another must be synchronized with test-and-set instructions. Most of the time would be taken up by unsuccessful test by the receiver. One way to speed the transfer would be to send an interrupt request to the receiving processor.

## 13-13

- (a) Mutual exclusion implies that each processor claims exclusive control of the resources alocated to it.
- (b) Critical section is a program sequence that must be comptely exocuted without interruptions by othe processors.

(Contined in next page)

# 13-13 (Cortinued)

- that a memory read is followed by a memory write without interruption from another processor,
- (d) <u>Semaphore</u> is a variable that indicates the number of processes attempting to use the critical section.
- Write memory operation so that the memory location cannot be accessed and middified by another processor.

## 11-14

Cache coherency is defined as the situation in which all cache refres of shared variables in a multiprocessor system have the same value at all times. A snoopy cache controller is a monitoring action that detects a write operation into any cache. The cache coherence problem can be resolved by either updading or invalidating all other cheche values of the written information.
